

## Today's Agenda

- Quiz 1 on next Tue.
- Quick Review
- Finish Program Proof
- Introduction to OCL

## Quick Review

- What is the difference between first-order logic and propositional logic?
- What is deductive verification? What is partial correctness?

## Introduction to OCL

- Model Driven Architecture
- Overview of OCL
- OCL By Example
- Summary

## What is MDA?

In **MDA**, the software development process is driven by the activity of **modeling**.

The **MDA** framework defines how to specify and transform **models** at different abstraction levels.

**MDA** is under supervision of the **Object Management Group (OMG)**.

More info. can be found at **MDA Explained: The Model Driven Architecture: Practice and Promise**, Addison-Wesley, 2003.

## The MDA Process

The **MDA** process consists of three steps:

- Build a model with a high level of abstraction, called **Platform Independent Model (PIM)**.
- Transform the **PIM** into one or more **Platform Specific Models (PSMs)**, i.e., models that are specified in some specific implementation technology.
- Transform the **PSMs** to code.

## PIM, PSM, and Code

## MDA Elements

- **Models** are the basis of MDA.
  - Models must be **consistent** and **precise**, and contain as much information as possible.
- **Modeling languages** describe models.
  - These languages must be **well-defined** to enable **automatic** transformation.
- **Transform. tools** do the dirty work.
  - PIM-to-PSM is more challenging than PSM-to-Code.
- **Transform. definitions** map one model to another.
  - These definitions must be **independent** of the tools.

## MDA Benefits

- **Portability**
  - PIMs can be transformed to different PSMs.
- **Productivity**
  - Developers work at a higher level abstraction.
- **Cross-platform interoperability**
  - PIMs serve as a bridge between different PSMs.
- **Easier maintenance and documentation**
  - Maintaining PIMs is much easier than maintaining code.

## Maturity Levels

The **maturity** level indicates the **gap** between the **model** and the **system**.

- ❑ Level 0: **No specification**
  - Everything is in mind.
- ❑ Level 1: **Textual description**
  - Informal English description.
- ❑ Level 2: **Text with Diagrams**
  - Use diagrams to help understanding.
- ❑ Level 3: **Models with Text**
  - Models have well-defined meaning
- ❑ Level 4: **Precise models**
  - Precise enough to enable automatic model-to-code transformation.
- ❑ Level 5: **Models only.**
  - Code is invisible.

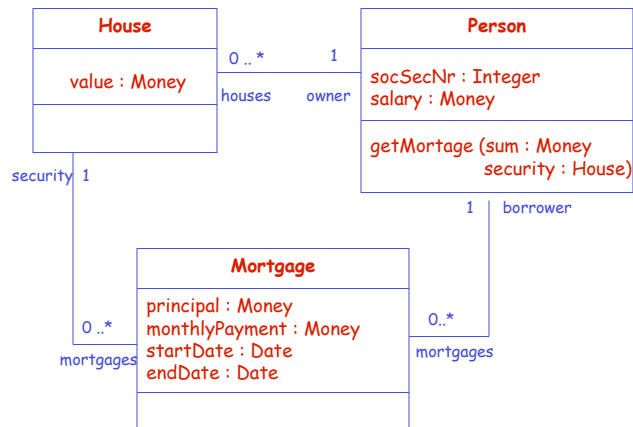

## Introduction to OCL

- ❑ Model Driven Architecture
- ❑ **Overview of OCL**
- ❑ OCL By Example
- ❑ Summary

## UML, OCL, and MDA

- UML uses **diagrams** to express software design.
  - Diagrams are easier to understand, but many properties cannot be expressed using diagrams alone.
- The use of OCL can add additional and necessary info. to UML diagrams.
  - OCL uses expressions that have solid mathematic foundation but still maintains the ease of use.
- Combining UML and OCL is necessary to construct models at maturity level 4
  - The application of MDA relies on Level 4 models.

## Example (1)

## Example (2)

Can we express the following info. on the diagrams?

- A person may have a mortgage on a house only if that house is owned by himself.
- The start date for any mortgage must be before the end date.
- The social security number of all persons must be unique.
- A new mortgage will be allowed only when the person's income is sufficient.
- A new mortgage will be allowed only when the counter-value of the house is sufficient.

## Example (3)

OCL can be used to express those info.:

```
context Mortgage
inv: security.owner = borrower
```

```
context Mortgage
inv: startDate < endDate
```

```
context Person
inv: Person::allInstances() -> isUnique (socSecNr)
```

```
context Person::getMortgage(sum: Money, security: House)
Pre: self.mortgages.monthlyPayment -> sum() <= self.salary * 0.30
```

```
context Person::getMortgage(sum: Money, security: House)
Pre: security.value >= self.mortgages.principal -> sum()
```

## Why these info.?

- ❑ Avoid any potential misunderstandings
  - Not everyone is aware of these constraints
  - People may make different assumptions.
- ❑ Enable automatic model analysis/transform.
  - Computer has no "intuition".
  - Software tools are possible only if the model contains complete information.
- ❑ Document your design decisions.

## Characteristics of OCL (1)

- ❑ OCL is a **constraint** and **query** language
  - A **constraint** is a restriction on one or more values of a model.
  - OCL can be used to write not only **constraints**, but any **query** expression.
  - It is proved that OCL has the same capability as SQL.

```
context: Flight::availableSeats () : Integer
body: plane.numberOfSeats - passengers -> size ()
```

## Characteristics of OCL (2)

- ❑ OCL has a **formal** foundation, but maintain the ease of use.
  - The result is a precise language that should be easily read and written by average developers.
- ❑ OCL is strongly-typed
  - This allows OCL expressions can be checked during modeling, before execution.
  - What is the benefit?
- ❑ OCL is a declarative language
  - OCL expressions state **what** should be done, but not **how**.

## Introduction to OCL

- ❑ Model Driven Architecture
- ❑ Overview of OCL
- ❑ **OCL By Example**
- ❑ Summary

## Main Classes

- **LoyaltyProgram** - one instance per each loyalty program
- **ProgramPartner** - a company which participates in a loyalty program
- **Customer** - a person who enters a loyalty program
- **CustomerCard** - information on an ID card
- **LoyaltyAccount** - keep track of the points
- **ServiceLevel** - administer the level of services
- **Transaction** - records transaction information

## The S&G Program

The program has four partners: a **supermarket**, a line of **gas stations**, a **car rental** service, and an **airline**:

- At the **supermarket**, the customer can use bonus points to purchase items. The customer earns five bonus points for any regular purchase over \$25.
- The **gas stations** offer a discount of 5 percent on every purchase.
- The **car rental** service offers 20 bonus points for every \$100 spent.
- The **airline** offers one bonus point for each 15 miles for every flight that is paid normally.

## Gold Card - Benefits

Customers with a **gold** card enjoy additional benefits:

- ❑ Every two months, the supermarket offers a free item with an average value of \$25.
- ❑ The gas stations offer a discount of 10 percent on every purchase.
- ❑ The car rental services offers a larger car for the same price.
- ❑ The airline offers a business seat for the economy class price.

## Gold Card - Conditions

Customers must meet at least one of the following conditions to get a **gold** card:

- ❑ Three sequential years of membership with an average **turnover** of \$5000.
- ❑ One year of member with a **turnover** of \$15,000

## Initial Values

- A loyalty account will always be initialized with zero points:

```
context LoyaltyAccount :: points
init: 0
```

- A customer card will always be valid at the moment it is issued

```
context CustomerCard :: valid
init: true
```

## Derived Attributes

Derived attributes are attributes whose values can be obtained from other attributes.

For instance, the attribute `printedName` of `CustomerCard` is determined based on the `name` and `title` of the card owner.

```
context CustomerCard::printedName
derive: owner.title.concat(' ').concat(owner.name)
```

## Query Operations

Query operations are operations that do not change the state of the system.

For instance, suppose the class `LoyaltyProgram` has a query operation `getServices`, which returns all services offered by all program partners:

```
context LoyaltyProgram::getServices(): Set(service)
body: partners.deliveredServices -> asSet ()
```

## New attributes and operations

OCL expressions can also define new attributes and operations.

```
context LoyaltyAccount
def: turnover : Real = transactions.amount -> sum ()
```

```
context LoyaltyProgram
def: getServicesByLevel(levelName: String): Set(Service)
= levels -> select (name = levelName).availableServices ->asSet ()
```

## Invariants

An **invariant** is a **constraint** that should be true for an object during its **complete** lifetime.

**Invariants** usually represent rules that should hold for the real-life objects after which the software objects are modeled.

## Invariants on Attributes

□ A reasonable rule for every loyalty program is to require that every customer is of legal age.

```
context Customer
inv: ofAge: age >= 18
```

□ Another example is that in a **CustomerCard** object, **validFrom** should be earlier than **goodThru**.

```
context CustomerCard
inv: checkDates: validFrom.isBefore(goodThru)
```

## Invariants on Associated Objects

Invariants can also express rules for **associated objects**, which are referred to by **rolenames**.

```
context CustomerCard
inv: ofAge: owner.age >= 18
```

**Question:** How do you decide where to put this invariant?

## Using Association Classes

❑ Association classes do not have **rolenames**; they are referred to by their class names.

```
context LoyaltyProgram
inv: knownServiceLevel: levels -> includesAll(Membership.currentLevel)
```

❑ Association classes can also be used as a context.

```
context Membership
inv: correctCard: participants.cards -> includes (self.card)
```

## Collections

Often, the **multiplicity** of an association is greater than 1, thereby linking one object to a **collection** of objects of the associated class.

OCL provides a wide range of **predefined** operations to manipulate a collection of objects. These operations are invoked by placing an **arrow** between the **rolename** and the **operation**.

Note that a user-defined operation is invoked using a **dot** notation.

## Collection Operations (1)

- size : returns the size of a collection

```
context LoyaltyProgram
inv: minServices: partners.deliveredServices -> size () >= 1
```

- select : takes an OCL expression as parameter, and returns a subset such that the expression is true for all the elements in the subset

```
context Customer
inv: sizesAgree:
  programs -> size() = cards -> select (valid = true) -> size ()
```

## Collection Operations (2)

□ **forall** : takes an OCL expression, and returns true if the expression is true for all elements in the collection, and false otherwise.

```
context LoyaltyProgram
inv: noAccounts: partners.deliveredServices -> forall (
  pointsEarned = 0 and pointsBurned = 0 )
  implies Membership.account -> isEmpty ()
```

Note that defining a constraint for a class already implies that the condition holds for all instances of the class.

## Collection Operations (3)

□ **collect** : returns the set of all values for a certain attribute of all objects in the collection

```
context LoyaltyProgram
inv: totalCountOfCustomers:
  participants -> size ()
  = partners -> collect (numberOfCustomers) -> sum()
```

□ Note that the dot notation can be used as an abbreviation for applying the collect operation.

```
context LoyaltyProgram
inv: totalCountOfCustomers:
  participants -> size ();
  = partners.numberOfCustomers -> sum()
```

## Collection Operations (4)

- `notEmpty` : return true when the collect has at least one element
- `includes (object)` : return true if object is an element of the collection
- `union (collection)` : return a collection that holds both collections.
- `intersection (collection)` : return a collection that holds all elements in both collections.

## Set vs Bag (1)

- A **set** is a collection in which each element is unique. A **bag** is a collection in which elements may be duplicated.
- In OCL, navigation through just one association with multiplicity greater than 1 generates a **set**; and navigation through more than one such association generates a **bag**.

## Set vs Bag (2)

Does the following OCL expression specify the invariant that attribute `numberOfCustomers` in class `ProgramPartner` holds the number of customers who participate in one or more loyalty programs offered by this program partner?

```
context ProgramPartner
inv: numberOfParticipants:
    numberOfCustomers
    = programs.participants -> size ()
```

## OrderedSets vs. Sequences

- An `OrderedSet` is a set in which the elements are ordered; a `sequence` is a bag in which the elements are ordered.
- Navigation through a single association marked `{ordered}` generates an `OrderedSet`; navigation through more than one such association generates a `sequence`.

```
context LoyalProgram
inv: firstLevel:
    levels -> first ().name = 'Silver'
```

## Pre-/Post-condition

- **Preconditions** and **postconditions** are constraints that specify the applicability and effect of an operation without stating an algorithm or implementation.

```
context LoyalAccount::isEmpty () : Boolean
pre: -- none
post: result = (points = 0)
```

## Previous values in postcondition

- A **postcondition** expression can refer to values at the start of the operation or upon completion of the operation.

```
context Customer::birthdayHappens ()
post: age = age@pre + 1
```

- It is also possible to refer to the pre-value of a query operation.

```
context Service::upgradePointsEarner (amount: Integer)
post: calcPoints () = calcPoints@pre() + amount
```

## Inheritance (1)

- In the R&L example, the program partners want to limit the number of bonus points they give away; they set a maximum of 10000 points to be earned using services of one partner.

```
context ProgramPartner
inv: totalPoints:
    deliveredServices.transactions.points -> sum() < 10000
```

## Inheritance (2)

- The predefined operation `oclIsTypeOf` can be used to determine if an element of a collection is an instance of a class.

```
context ProgramPartner
inv: totalPointsEarning:
    deliveredServices.transactions
    -> select ( oclIsTypeOf (Earning) ).points -> sum () < 10000
```

## Let expression

- The **let** expression enables to define a "local" variable.

```
context CustomerCard
inv: let correctDate : Boolean =
    self.validFrom.isBefore (Date::now) and
    self.goodThru.isAfter (Date::now)
in
    if valid then
        correctDate = true
    else
        correctDate = false
```

## Comments

- **Comments** are necessary to help understanding.
  - A line comment is indicated by two minus signs: --
  - Comments that span more than one line can be enclosed between /\* and \*/.

## Introduction to OCL

- Model Driven Architecture
- Overview of OCL
- OCL By Example
- Summary

## Summary

- MDA is the ultimate paradigm for software development.
- OCL is a declarative, strongly-typed query and constraint language.
- The combination of OCL and UML allows precise models to be built, which is a crucial step towards MDA.
- Additional info. that can be added by OCL include (1) initial values; (2) query operations; (3) invariants; and (4) pre-/post-conditions.
