

Today's Agenda

- HW 2 Out, Due on Oct. 15
- Presentation Signup
- Quick Review
- Continue on **Monitor**

Monitor

- **Introduction**
- Monitors in Java
- Signaling Disciplines
- Implementing Monitors
- Monitor-based Solutions

Motivation

Semaphores were defined before the concepts of **data encapsulation** and **information hiding** were introduced.

In addition, a semaphore can be used for both **mutual exclusion** and **conditional synchronization**, which makes it difficult to distinguish them.

What is it?

Monitor is a high-level synchronization construct that supports **data encapsulation** and **information hiding**.

It encapsulates shared data, operations on the data, and the required synchronization for accessing the data.

Important: **Threads** are **active**, while **monitors** are **passive**.

OO Definition

A **monitor** class **N** with **m** data members, **n** condition variables, and **k** methods.

```
monitor N {
    private Data d1, d2, ..., dm;           // data members
    private ConditionVariable v1, v2, ..., vn; // condition vars

    public N() { ... };                     // constructor
    public/private void M1 (...) { ... }    // access methods
    public/private void M2 (...) { ... }
    ...
    public/private void Mk (...) { ... }
}
```

Mutual Exclusion

Mutual exclusion is provided automatically by **monitor** implementation.

If a thread calls a **monitor** method, but another thread is already executing inside the monitor, the calling thread waits in an **entry** queue.

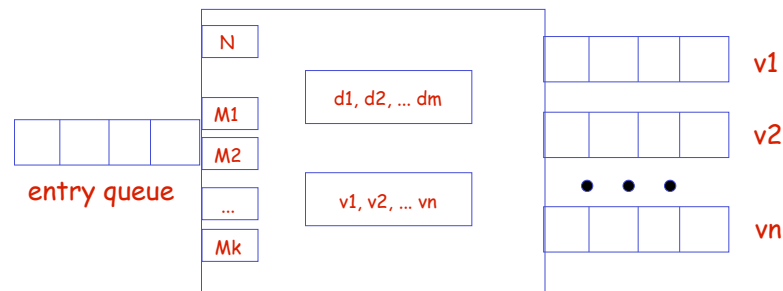

Conditional Synchronization

Conditional synchronization is programmed using condition variables.

A **condition variable** denotes a queue of threads that are waiting for a specific condition to become true.

A monitor has one **entry queue** and one queue associated with each **condition variable**.

Graphic View

Wait Operation

A thread that is executing inside a **monitor** method blocks itself on condition variable **v** by executing **v.wait ()**.

Execution of operation **wait** releases **mutual exclusion** and blocks the thread on the rear of the queue for **v**.

Important: Threads blocked on a condition variable are **outside** the monitor.

Signal Operation

A thread blocked on condition variable **v** is awakened by the execution of **v.signal ()**.

If there are no threads blocked on **v**, this signal operation has no effect; otherwise, it awakens the thread at the front of the queue for **v**.

Signaling Discipline

There are different types of signaling disciplines. For now, we will assume the "signal and continue", or **SC**, discipline.

The thread executes a **signal** operation to awaken a waiting thread, the thread continues executing in the monitor and the awakened thread is moved to the **entry** queue.

Empty & Length Operations

The execution of **v.empty ()** returns **true** if the queue for **v** is empty, and **false** otherwise.

The execution of **v.length ()** returns the length of the queue for **v**.

An Example

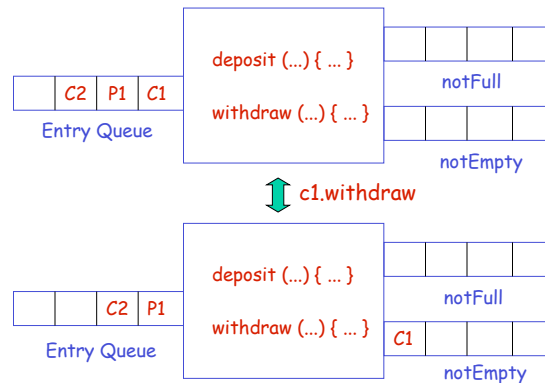

```

monitor BoundedBuffer {
  private int fullSlots = 0;
  private int capacity = 0;
  private int[] buffer = null;
  private int in = 0, out = 0;
  private ConditionVariable notFull = new ConditionVariable ();
  private ConditionVariable notEmpty = new ConditionVariable ();

  public BoundedBuffer (int capacity) {
    this.capacity = capacity;
    buffer = new int [ capacity ];
  }
  public void deposit (int value) {
    while (fullSlots == capacity) {
      notFull.wait ();
    }
    buffer[in] = value;
    in = (in + 1) % capacity;
    ++ fullSlots;
    notEmpty.signal ();
  }
  public int withdraw () {
    int value;
    while (fullSlots == 0) {
      notEmpty.wait ();
    }
    value = buffer[out];
    out = (out + 1) % capacity;
    -- fullSlots;
    notFull.signal ();
    return value;
  }
}

```

An Example (cont'd)

An Example (cont'd)

An Example (cont'd)

An Example (cont'd)

What if we change `while` to `if` in methods `deposit` and `withdraw`?

Monitor

- Introduction
- **Monitors in Java**
- Signaling Disciplines
- Implementing Monitors
- Monitor based Solutions

Java Monitor (1)

Java built-in monitor is different from the monitors we have defined.

Mutual exclusion is only enforced for **synchronized** methods.

There are no explicit **condition variables** in Java. Instead, each object is associated with only one implicit **condition variable**.

Java Monitor (2)

Java Monitor (3)

- Each Java object is implicitly associated with a **lock**.
- A thread must hold an object's **lock** before it can execute a **wait**, **notify**, or **notifyAll** operations.
- When a thread executes **wait**, it releases the object's **lock** and waits in the implicit condition queue.
- **notify** operations do not guarantee FCFS.
- A notified thread must reacquire the **lock** before it resumes execution.

notify vs. notifyAll

The fact that Java monitors have only one condition variable has important implications.

As threads waiting on the same implicit condition variable may be waiting for different conditions to become true, **notify** operations must be handled carefully.

notify vs. notifyAll (cont'd)

```
public final class BinarySemaphore extends Semaphore {
    public BinarySemaphore (int initialPermits) {
        super(initialPermits);
        if (initialPermits != 0 || initialPermits != 1) {
            throw new IllegalArgumentException("initial value must be 0 or 1.");
        }
    }
    synchronized public void P () {
        while (permits == 0) {
            try { wait (); } catch (InterruptedException ex) {};
        }
        permits = 0;
        notifyAll ();
    }
    synchronized public void V () {
        while (permits == 1) {
            try { wait (); } catch (InterruptedException ex) {};
        }
        permits = 1;
        notifyAll ();
    }
}
```

notify vs. notifyAll (cont'd)

What happens if we change **notifyAll** to **notify**?

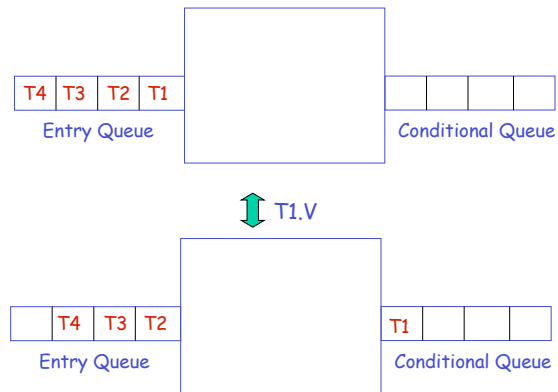

```
public final class BinarySemaphore extends Semaphore {
    public BinarySemaphore (int initialPermits) {
        super(initialPermits);
        if (initialPermits != 0 && initialPermits != 1) {
            throw new IllegalArgumentException("initial value must be 0 or 1.");
        }
    }
    synchronized public void P () {
        while (permits == 0) {
            try { wait (); } catch (InterruptedException ex) {};
        }
        permits = 0;
        notify ();
    }
    synchronized public void V () {
        while (permits == 1) {
            try { wait (); } catch (InterruptedException ex) {};
        }
        permits = 1;
        notify ();
    }
}
```

notify vs notifyAll (cont'd)

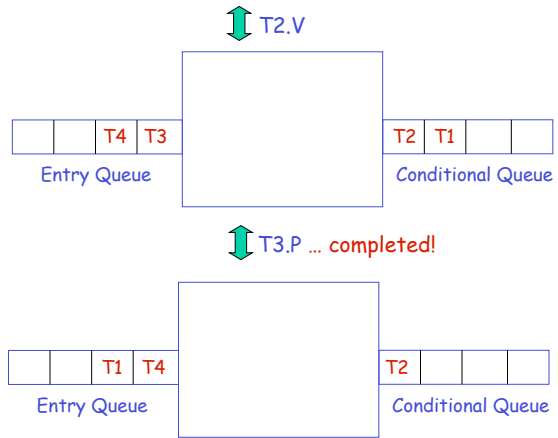

Let s be a binary semaphore initialized as 1.

<u>T1</u>	<u>T2</u>	<u>T3</u>	<u>T4</u>
$s.V$	$s.V$	$s.P$	$s.P$

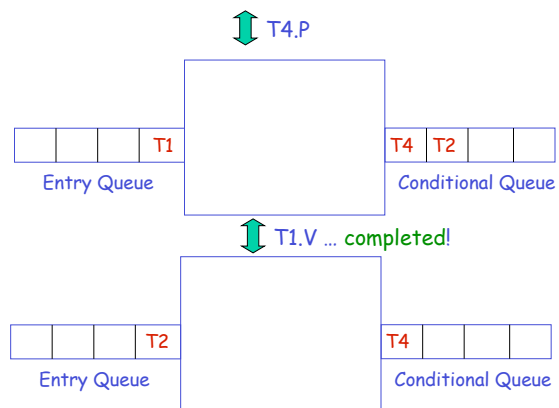

notify vs. notifyAll (cont'd)

notify vs. notifyAll (cont'd)

notify vs. notifyAll (cont'd)

notify vs. notifyAll (cont'd)

notify vs. notifyAll (cont'd)

Using **notifyAll** instead of **notify** unless the following requirements are met:

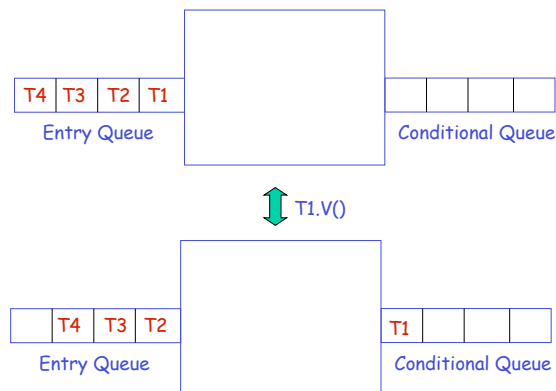

- All **waiting** threads are waiting on the exact same condition.
- Each notification should enable exactly one thread to continue.

while vs if

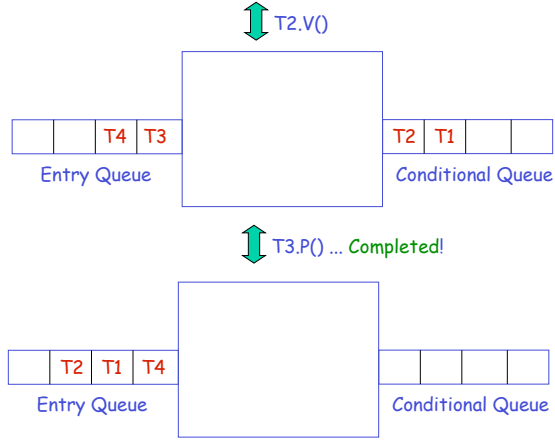

What if we change **while** to **if**?

```
public final class BinarySemaphore extends Semaphore {
    public BinarySemaphore (int initialPermits) {
        super(initialPermits);
        if (initialPermits != 0 || initialPermits != 1) {
            throw new IllegalArgumentException("initial value must be 0 or 1.");
        }
    }
    synchronized public void P () {
        if (permits == 0) {
            try { wait (); } catch (InterruptedException ex) {};
        }
        permits = 0;
        notifyAll ();
    }
    synchronized public void V () {
        if (permits == 1) {
            try { wait (); } catch (InterruptedException ex) {};
        }
        permits = 1;
        notifyAll ();
    }
}
```

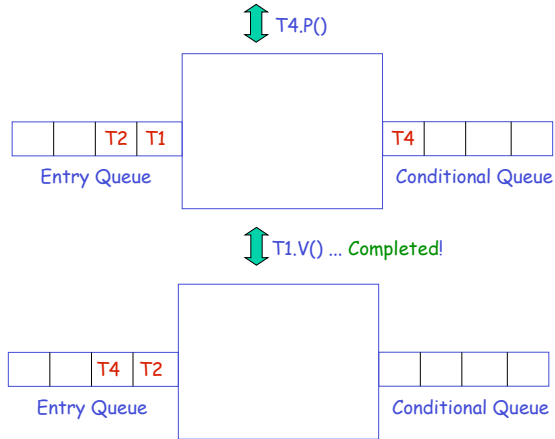

while vs. if (cont'd)

while vs. if (cont'd)

while vs. if (cont'd)

while vs. if (cont'd)

while vs. if (cont'd)

In general, with the **SC** discipline, use **while** instead of **if**, unless the following requirement is met:

- After a thread **T** is awakened, no other threads can change the condition **T** was waiting on before **T** re-enter the monitor.

Revisit the BB example

What if we change **while** to **if** and/or **notify** to **notifyAll**?

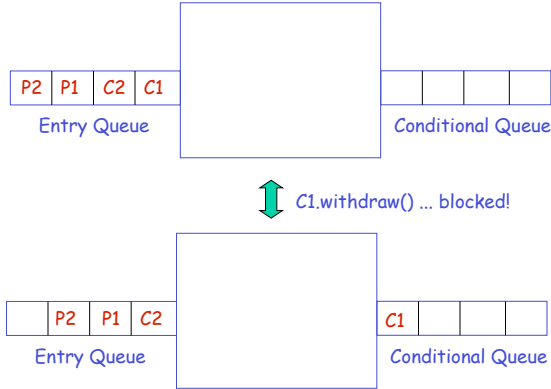

Revisit BB (cont'd)

```
final class BoundedBuffer {
    private int fullSlots = 0;
    private int capacity = 0;
    private int[] buffer = null;
    private int in = 0, out = 0;

    public BoundedBuffer (int capacity) {
        this.capacity = capacity;
        buffer = new int [ capacity ];
    }
    public synchronized void deposit (int value) {
        while (fullSlots == capacity) {
            try { wait(); } catch (InterruptedException ex) {}
        }
        buffer[in] = value;
        in = (in + 1) % capacity;
        if (fullSlots ++ == 0) {
            notify ();
        }
    }
    public synchronized void withdraw () {
        int value;
        while (fullSlots == 0) {
            try { wait (); } catch (InterruptedException ex) {}
        }
        value = buffer[out];
        out = (out + 1) % capacity;
        if (fullSlots -- == capacity) {
            notify ()
        }
        return value;
    }
}
```

Revisit BB

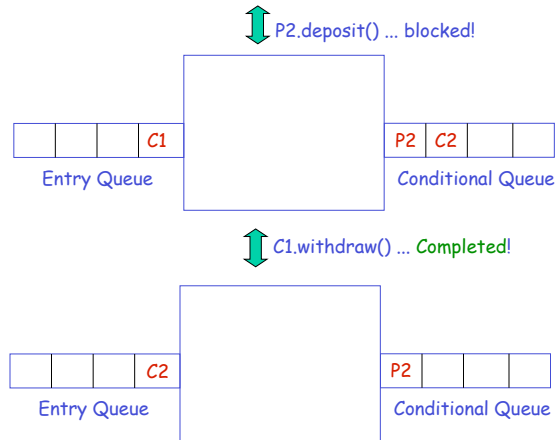

Assume the buffer has one slot and is empty.

Revisit BB (cont'd)

Revisit BB (cont'd)

Revisit BB (cont'd)

Revisit MutexLock implementation

Why do we use `notify` instead of `notifyAll`, and `if` instead of `while`?

MutexLock

```
public final class MutexLock {
    private Thread owner = null;
    private int waiting = 0;
    public int count = 0;
    public boolean free = true;

    public synchronized void lock () {
        if (free) {
            count = 1; free = false; owner = Thread.currentThread ();
        }
        else if (owner == Thread.currentThread ()) { ++ count; }
        else {
            ++ waiting;
            try { wait(); } catch (InterruptedException ex) {}
            count = 1; owner = Thread.currentThread ();
        }
    }

    public synchronized void unlock () {
        if (owner != null) {
            if (owner == Thread.currentThread ()) {
                -- count;
                if (count == 0) {
                    owner = null;
                    if (waiting > 0) {
                        -- waiting;
                        notify();
                    }
                }
                else { free = true; return; }
            }
            else return;
        }
        }
        throw new OwnerException ();
    }
}
```

MutexLock (cont'd)

```

public final class MutexLock {
    private Thread owner = null;
    private int waiting = 0;
    public int count = 0;
    public boolean free = true;

    public synchronized void lock () {
        if (free) {
            count = 1; free = false; owner = Thread.currentThread ();
        }
        else if (owner == Thread.currentThread()) { ++ count; }
        else {
            ++ waiting;
            try { wait(); } catch (InterruptedException ex) {}
            free = false;
            count = 1; owner = Thread.currentThread ()
        }
    }

    public synchronized void unlock () {
        if (owner != null) {
            if (owner == Thread.currentThread()) {
                -- count;
                if (count == 0) {
                    owner = null;
                    if (waiting > 0) {
                        -- waiting;
                        free = true;
                        notify();
                    }
                }
                else { free = true; return; }
            }
            else return;
        }
        throw new OwnerException ();
    }
}

```

synchronized block

Consider the following code segment:

```

synchronized (o) {
    /* block of code */
}

```

synchronized block (cont'd)

```
public synchronized void foo (o) {
    /* block of code */
}
```

```
public void foo (o) {
    synchronized (this) {
        /* block of code */
    }
}
```

synchronized block (cont'd)

```
public final class BinarySemaphore {
    int vPermits = 0, pPermits = 0;
    Object allowP = null, allowV = null;

    public BinarySemaphore (int initialPermits) {
        if (initialPermits != 0 || initialPermits != 1) {
            throw new IllegalArgumentException("initial value must be 0 or 1.");
        }
        pPermits = initialPermits;
        vPermits = 1 - vPermits;
        allowP = new Object ();
        allowV = new Object ();
    }

    public void P () {
        synchronized (allowP) {
            -- pPermits;
            if (pPermits < 0) {
                try { allowP.wait (); } catch (InterruptedException ex) {}
            }
        }
        synchronized (allowV) {
            ++ vPermits;
            if (vPermits <= 0) {
                allowV.notify ();
            }
        }
    }

    public void V () {
        synchronized (allowV) {
            -- vPermits;
            if (vPermits < 0) {
                try { allowV.wait (); } catch (InterruptedException ex) {}
            }
        }
        synchronized (allowP) {
            ++ pPermits;
            if (pPermits <= 0) {
                allowP.notify ();
            }
        }
    }
}
```

Monitor

- Introduction
- Monitors in Java
- Signaling Disciplines
- Implementing Monitors
- Monitor based Solutions

Signaling Discipline

A thread blocked on a condition variable `c` is awakened by the execution of `c.signal ()`.

If there are no threads blocked on `c`, the signal operation has no effect. Otherwise, the signal operation awakens the thread in the front of the queue for `c`.

What happens next depends on the signaling disciplines.

Signal-and-Continue (SC)

When a thread executes `c.signal ()`.

- ❑ If there are no threads waiting on `c`, this operation has no effects.
- ❑ Otherwise, the signaling thread awakens one thread waiting on `c`, and continues execution inside monitor.
- ❑ The awakened thread does not resume execution immediately. Instead, it is moved from the `conditional` queue to the `entry` queue.

Signal-and-Continue (SC) (cont'd)

When a thread executes `c.wait`:

- ❑ The thread releases `mutual exclusion` to allow a thread on the `entry` queue to enter the monitor.
- ❑ The thread then blocks itself on the condition queue for `c`.

Signal-and-Continue (SC) (cont'd)

When a thread exits a monitor:

- ❑ The thread releases mutual exclusion to allow a thread on the **entry** queue to enter the monitor.

Signal-and-Urgent-Wait (SU)

When a thread executes **c.signal ()**.

- ❑ If there are no threads waiting on **c**, this operation has no effects.
- ❑ Otherwise, the signaling thread awakens one thread waiting on **c**, and blocks itself in a queue called the **reentry** queue.
- ❑ The awakened thread reenters the monitor immediately.

Signal-and-Urgent-Wait (SU) (cont'd)

When a thread executes `c.wait ()`.

- If the `reentry` queue is not empty, the thread awakens a thread from the `reentry` queue before it blocks itself on the queue for `c`.
- Otherwise, the thread releases `mutual exclusion` (to allow a thread on the `entry` queue to enter the monitor) and then blocks itself on the queue for `c`.

Signal-and-Urgent-Wait (SU) (cont'd)

When a thread `exits` a monitor thread

- If the `reentry` queue is not empty, it awakens a thread from the `reentry` queue.
- Otherwise, it releases `mutual exclusion` (to allow a thread on the `entry` queue to enter the monitor).

Signal-and-Exit (SE)

SE is a special case of SU. When a thread executes an SE **signal** operation, it exits the monitor immediately.

Therefore, a **signal** statement is either the last statement of a method or it is followed immediately by a **return** statement.

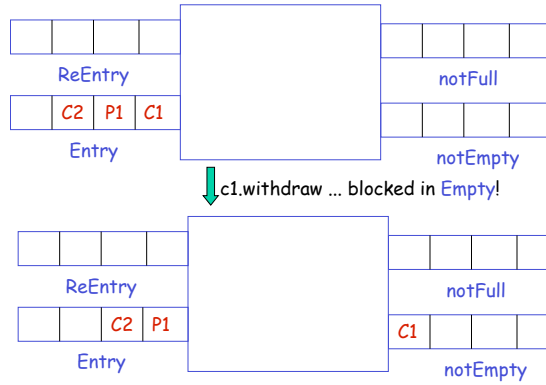

The awakened thread is the next thread to enter the monitor.

Signal-and-Exit (SE)

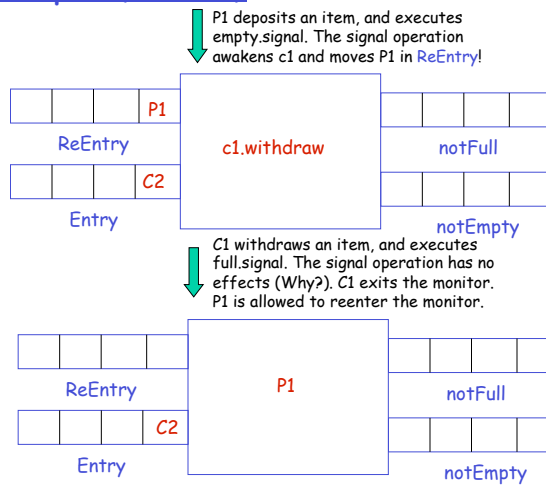

It has turned out that many signal statements do appear as the last statement in monitor methods.

Using SE semantics for these signal statements is more efficient. (Why?)

SU Example

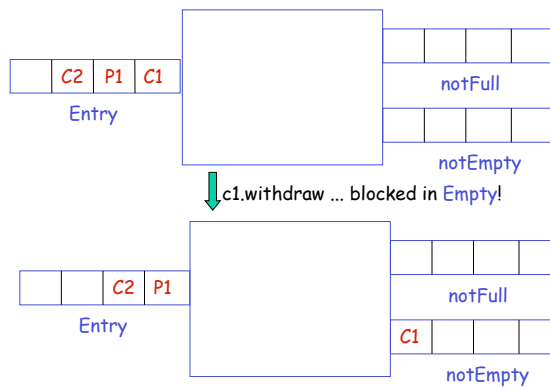

SU Example (cont'd)

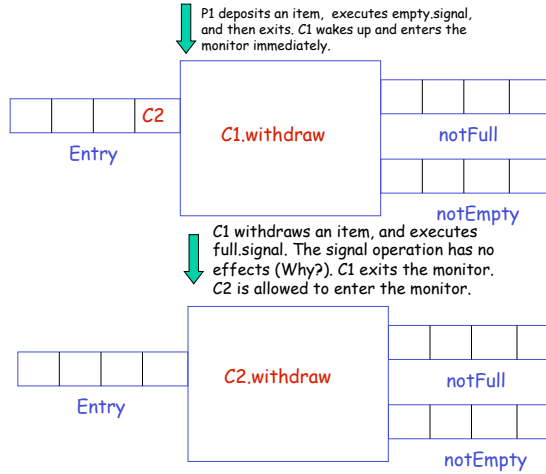

SU Example (cont'd)

SE Example

SE Example (cont'd)

SE Example (cont'd)

SC vs. SU

What is the essential difference between *SC* and *SU*?

Implications

If a thread executes an *SU* signal to notify another thread that a certain condition is true, this condition remains *true* when the signaled thread reenters the monitor. (However, this does not hold for an *SC* signal. Why?)

Implications: A *wait* operation does not have to be placed in a *while* loop.

Example

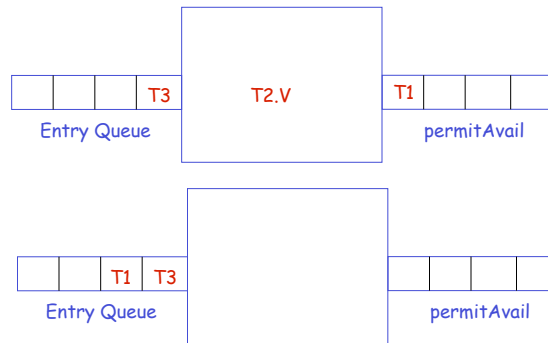

```
monitor CountingSemaphore {  
    private int permits;  
    private ConditionVariable permitAvail = new ConditionVariable ();  
    public CountingSemaphore (int initialPermits) {  
        permits = initialPermits;  
    }  
    public void P () {  
        if (permits == 0) {  
            permitAvail.wait ();  
        }  
        -- permits;  
    }  
    public void V () {  
        ++ permits;  
        permitAvail.signal ();  
    }  
}
```

Example (cont'd)

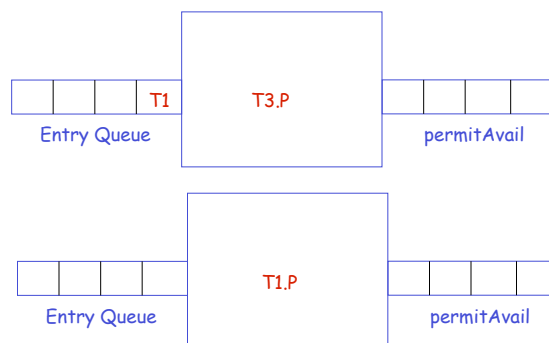

The simulation is incorrect if *SC* signals are used.
Why?

Example (cont'd)

Assume that T1 is blocked on `permitAvail` in P, T2 has just executed `++permits` in V, and T3 is waiting in the entry queue to execute a P operation.

Example (cont'd)

Example (cont'd)

What is the fundamental reason for this error?

The condition `permits > 0` is true when `T1` is awakened. However, `T1` does not resume execution immediately.

`T1` has to compete for mutual exclusion with other threads. When `T1` acquires mutual exclusion and reenters the monitor, the condition `permits > 0` is no longer true. (The condition was falsified by `T2`.)

Example (cont'd)

Can we fix this problem such that it still works with `SC` signal?

SC vs SU vs SE

With **SC**, a **wait** operation usually has to be placed in a **while** loop. This means that the relevant condition must be reevaluated after a **wait** operation.

With **SU**, an **if** statement can be used. However, the **signaling** thread will be blocked in the **reentry** queue, and needs to reenter the monitor before it exits. This represents an extra context switch.

With **SE**, both the cost of an extra evaluation and that of an extra context switch can be avoided.
(What is the catch?)

Revisit the example

Is there any other problem if we change **if** to **while**, assuming **SC** discipline?

Revisit the example (cont'd)

Assume that T1 is blocked on `permitAvail` in P, T2 has just executed `++permits` in V, and T3 is waiting in the entry queue to execute a P operation.

Revisit the example (cont'd)

Revisit the example (cont'd)

Revisit the example (cont'd)

At this point, we assume that thread T2' arrives and starts to execute a V operation inside the monitor. Before T2' exits the monitor, thread T3' arrives and waits in the entry queue to execute a P operation. Similarly, T3' will complete its P operation, and T1 will be blocked again.

Alternative implementation

```
monitor class CountingSemaphore {  
    private int permits;  
    private ConditionVariable permitAvail = new ConditionVariable ();  
    public CountingSemaphore (int initialPermits) {  
        permits = initialPermits;  
    }  
    public void P () {  
        -- permits;  
        if (permits < 0) {  
            permitAvail.wait ();  
        }  
    }  
    public void V () {  
        ++ permits;  
        permitAvail.signal ();  
    }  
}
```

Alternative Implementation (cont'd)

Is this implementation correct with SU discipline?
How about SC discipline?

Monitor

- Introduction
- Monitors in Java
- Signaling Disciplines
- **Implementing Monitors**
- Monitor based Solutions

SC Signaling

Each public **monitor** method is implemented as follows:

```
public ReturnType foo (...) {  
    mutex.P ();  
    /* body of foo */  
    mutex.V ();  
}
```

SC Signaling (cont'd)

```

final class ConditionVariable {
    private CountingSemaphore threadQue = new CountingSemaphore (0);
    private int numWaitingThreads = 0;
    public void waitC () {
        numWaitingThreads ++;
        threadQue.VP (mutex); // { mutex.V (); threadQue.P () }
        mutex.P ();
    }
    public void signalC () {
        if (numWaitingThreads > 0) {
            numWaitingThreads --;
            threadQue.V ();
        }
    }
    public void signalCall () {
        while (numWaitingThreads > 0) {
            -- numWaitingThreads;
            threadQueue.V ();
        }
    }
    public boolean empty () { return numWaitingThreads == 0; }
    public int length () { return numWaitingThreads; }
}

```

SU Signaling

Each public monitor method is implemented as follows:

```

public ReturnType foo (...) {
    mutex.P ();
    /* body of foo */
    if (reentryCount > 0)
        reentry.V ();
    else mutex.V ();
}

```

SU Signaling (cont'd)

```

final class ConditionVariable {
    private CountingSemaphore threadQue = new CountingSemaphore (0);
    private int numWaitingThreads = 0;
    public void waitC () {
        numWaitingThreads ++;
        if (reentryCount > 0) threadQue.VP (reentry); // { reentry.V(); threadQue.P() }
        else threadQue.VP (mutex); // { mutex.V(); threadQue.P() }
        -- numWaitingThreads;
    }
    public void signalC () {
        if (numWaitingThreads > 0) {
            ++ reentryCount;
            reentry.VP (threadQue); // { threadQue.V(); reentry.P() }
            -- reentryCount;
        }
    }
    public boolean empty () { return numWaitingThreads == 0; }
    public int length () { return numWaitingThreads; }
}

```

A monitor toolbox for Java

A monitor toolbox is a program unit that can be used to simulate the monitor construct.

The Java monitor toolbox consists of two classes, **MonitorSC** and **MonitorSU**.

Why a monitor toolbox?

A simulated monitor can be implemented in languages that do not support monitors directly.

Different versions of monitors can be created for different signaling disciplines.

A simulated monitor can be extended to support testing and debugging.

How to use a Java monitor toolbox

A regular Java class can be made into a **monitor** class by doing the following:

- ❑ extend class **MonitorSC** or **MonitorSU**
- ❑ use operations **enterMonitor** and **exitMonitor** at the start and end of each public method.
- ❑ declar as many **ConditionVariables** as needed
- ❑ use operations **waitC ()** and **signalC/signalCall ()** on **ConditionVariables**

MonitorSC

```

public class MonitorSC {
    private BinarySemaphore mutex = new BinarySemaphore (1);
    protected final class ConditionVariable {
        private CountingSemaphore threadQue = new CountingSemaphore (0);
        private int numWaitingThreads = 0;
        public void signalC () {
            if (numWaitingThreads > 0) {
                numWaitingThreads--;
                threadQue.V();
            }
        }
        public void signalCall () {
            while (numWaitingThreads > 0) {
                -- numWaitingThreads;
                threadQue.V();
            }
        }
        public void waitC () {
            numWaitingThreads++;
            threadQue.VP(mutex); // { mutex.V(); threadQue.P() }
            mutex.P();
        }
        public boolean empty () { return numWaitingThreads == 0; }
        public int length () { return numWaitingThreads; }
    }

    protected void enterMonitor () { mutex.P(); }
    protected void exitMonitor () { mutex.V(); }
}

```

MonitorSU

```

public class MonitorSU {
    private BinarySemaphore mutex = new BinarySemaphore (1);
    private BinarySemaphore reentry = new BinarySemaphore (0);
    private int reentryCount = 0;
    protected final class ConditionVariable {
        private CountingSemaphore threadQue = new CountingSemaphore (0);
        private int numWaitingThreads = 0;
        public void signalC () {
            if (numWaitingThreads > 0) {
                ++ reentryCount;
                reentry.VP (threadQue); // { threadQue.V(); reentry.P() }
                -- reentryCount;
            }
        }
        public void signalC_and_exitMonitor () {
            if (numWaitingThreads > 0) threadQue.V();
            else if (reentryCount > 0) reentry.V();
            else mutex.V();
        }
        public void waitC () {
            numWaitingThreads++;
            if (reentryCount > 0) threadQue.VP (reentry); // { reentry.V(); threadQue.P() }
            else threadQue.VP(mutex); // { mutex.V(); threadQue.P() }
            -- numWaitingThreads;
        }
        public boolean empty () { return numWaitingThreads == 0; }
        public int length () { return numWaitingThreads; }
    }

    protected void enterMonitor () { mutex.P(); }
    protected void exitMonitor () {
        if (reentryCount > 0) reentry.V ();
        else mutex.V();
    }
}

```

Example

```
final class BoundedBuffer extends MonitorSC {
    ...
    private ConditionVariable notFull = new ConditionVariable ();
    private ConditionVariable notEmpty = new ConditionVariable ();
    ...

    public void deposit (int value) {
        enterMonitor ();
        while (fullSlots == capacity) {
            notFull.waitC ();
        }
        buffer[in] = value;
        in = (in + 1) % capacity;
        ++ fullSlots;
        notEmpty.signalC ();
        exitMonitor ();
    }
    ...
}
```

Example (cont'd)

```
final class BoundedBuffer extends MonitorSU {
    ...
    private ConditionVariable notFull = new ConditionVariable ();
    private ConditionVariable notEmpty = new ConditionVariable ();
    ...

    public void deposit (int value) {
        enterMonitor ();
        while (fullSlots == capacity) {
            notFull.waitC ();
        }
        buffer[in] = value;
        in = (in + 1) % capacity;
        ++ fullSlots;
        notEmpty.signalC_and_exitMonitor ();
    }
    ...
}
```

- Monitors in Java
- Signaling Disciplines
- Implementing Monitors
- Monitor based Solutions

Dining Philosopher

```
while (true) {  
    /* thinking */  
    dp.pickUp (i);  
    /* eating */  
    dp.putDown (i)  
}
```

Dining Philosophers (Solution 1)

```

monitor class DiningPhilosopher {
    final int n = ... ; // number of philosophers
    final int thinking = 0, hungry = 1, eating = 2;
    int state[] = new int [n];
    ConditionVariable[] self = new ConditionVariable [n];
    DiningPhilosopher () {
        for (int i = 0; i < n; i++) state[i] = thinking;
        for (int j = 0; j < n; j++) self[j] = new ConditionVariable ();
    }
    public void pickUp (int i) {
        state[i] = hungry;
        test(i);
        if (state[i] != eating) self[i].wait ();
    }
    public void putDown (int i) {
        state[i] = thinking;
        test( (i-1) % n);
        test( (i+1) % n);
    }
    private void test (int k) {
        if ( (state[k] == hungry) && (state[(k-1)%n] != eating) && (state[(k+1)%n] != eating)) {
            state[k] = eating;
            self[k].signal ();
        }
    }
}

```

Dining Philosophers (Solution 2)

```

monitor class DiningPhilosopher {
    final int n = ... ; // number of philosophers
    final int thinking = 0, hungry = 1, starving = 2, eating = 3;
    int state[] = new int [n];
    ConditionVariable[] self = new ConditionVariable [n];
    DiningPhilosopher () {
        for (int i = 0; i < n; i++) state[i] = thinking;
        for (int j = 0; j < n; j++) self[j] = new ConditionVariable ();
    }
    public void pickUp (int i) {
        state[i] = hungry;
        test(i);
        if (state[i] != eating) self[i].wait ();
    }
    public void putDown (int i) {
        state[i] = thinking;
        test( (i-1) % n);
        test( (i+1) % n);
    }
    private void test (int k) {
        if ( (state[k] == hungry || state[k] == starving) && (state[(k-1)%n] != eating &&
state[(k-1)%n] != starving) && (state[(k+1)%n] != eating && state[(k+1)%n] != starving)) {
            state[k] = eating;
            self[k].signal ();
        }
        else if ((state[k] == hungry) && (state[(k-1)%n] != starving) && (state[(k+1)%n] !=
starving)) {
            state[k] = starving;
        }
    }
}

```

R>W.1

```

monitor class RW {
    int readerCount = 0; boolean writing = false;
    ConditionVariable readerQue = new ConditionVariable ();
    ConditionVariable writerQue = new ConditionVariable ();
