## Why Data Structure Repair is important

- All software use some sort of data structure underneath.
- Data structure corruption might result into software crash
- User intervention might not be an option for corruption repair, e.g., real time systems.

## Goal:

- Automatically repair data structures to prevent software crash.
- Perform such repair actions effectively and in a time efficient manner. Cannot wait forever!

Dynamic Symbolic Data Structure Repair

3

## Example: Single linked list

```
public class LinkedList {
    Node header;
    // ..
    public boolean repOk() {
        Node n = header;
        if (n == null)
            return true;
        int length = n.value;
        int count = 1;
        while(n.next != null) {
            count += 1;
            n = n.next;
            if (count > length)
                return false;
        }
        if (count != length)
            return false;

        return true;
    }
}
```

```
public class Node {
    int value;
    Node next;
    // ..
}
```

First node has a value that is equal to the number of nodes in the list.

Dynamic Symbolic Data Structure Repair

4

```

public class LinkedList {
    Node header;
    // ..
    public boolean repOk() {
        Node n = header;
        if (n == null)
            return true;
        int length = n.value;
        int count = 1;
        while(n.next != null) {
            count += 1;
            n = n.next;
            if (count > length)
                return false;
        }
        if (count != length)
            return false;
        return true;
    }
}

```

```

graph TD
    A(n1 == null) -- F --> B(n1.next != null)
    A -- T --> AT(( ))
    B -- F --> C(2 > n1.next)
    B -- T --> BT(( ))
    C -- F --> D(n2.next != null)
    C -- T --> CT(( ))
    D -- F --> E(3 > n1.next)
    D -- T --> DT(( ))
    E -- F --> F(n3.next != null)
    E -- T --> ET(( ))
    F -- F --> G(3 != n1.value)
    F -- T --> FT(( ))
    G -- F --> H(return false)
    G -- T --> I(return true)

```

Dynamic Symbolic Data Structure Repair 5

### Our approach to the problem:

```

public class LinkedList {
    Node header;
    // ..
    public boolean repOk() {
        Node n = header;
        if (n == null)
            return true;
        int length = n.value;
        int count = 1;
        while(n.next != null) {
            count += 1;
            n = n.next;
            if (count > length)
                return false;
        }
        if (count != length)
            return false;
        return true;
    }
}

```

```

public class Node {
    int value;
    Node next;
    // ..
}

```

First node has a value that is equal to the number of nodes in the list.

Dynamic Symbolic Data Structure Repair 6

## Our approach to the problem:

```
public class LinkedList {
    Node header;
    // ..
    public boolean repOk() {
        Node n = header;
        if (n == null)
            return true;
        int length = n.value;
        int count = 1;
        while(n.next != null) {
            count += 1;
            n = n.next;
            if (count > length)
                return false;
        }
        if (count != length)
            return false;

        return true;
    }
}
```

```
public class Node {
    int value;
    Node next;
    // ..
}
```

First node has a value that is equal to the number of nodes in the list.

Constraints:

```
n1 != null
n1.next != null
2 <= n1.value
n2.next != null
3 <= n1.value
n3.next == null
3 != n1.value  3 == n1.value
```

Solve

$3 = n1.value$

Dynamic Symbolic Data Structure Repair

7

## Existing state of the art tool: Juzi

### Few facts about Juzi:

- Developed by Bassem Elkarablieh and Sarfaraz Khurshid of University of Texas at Austin.

▪ <http://users.ece.utexas.edu/~elkarabl/Juzi/index.html>

- Assumes last instance and field accessed before returning are corrupt.
- Uses constraint solving techniques for primitive fields.
- Uses exhaustive search technique for reference fields.
- Does not suggest new instances of classes.

Dynamic Symbolic Data Structure Repair

8

## Juzi's approach in solving our example problem:

```

public class LinkedList {
    Node header;
    // ..
    public boolean repOk() {
        Node n = header;
        if (n == null)
            return true;
        int length = n.value;
        int count = 1;
        while(n.next != null) {
            count += 1;
            n = n.next;
            if (count > length)
                return false;
        }
        if (count != length)
            return false;

        return true;
    }
}

```

```

public class Node {
    int value;
    Node next;
    // ..
}

```

First node has a value that is equal to the number of nodes in the list.

## Juzi's approach in solving our example problem:

```

public class LinkedList {
    Node header;
    // ..
    public boolean repOk() {
        Node n = header;
        if (n == null)
            return true;
        int length = n.value;
        int count = 1;
        while(n.next != null) {
            count += 1;
            n = n.next;
            if (count > length)
                return false;
        }
        if (count != length)
            return false;

        return true;
    }
}

```

```

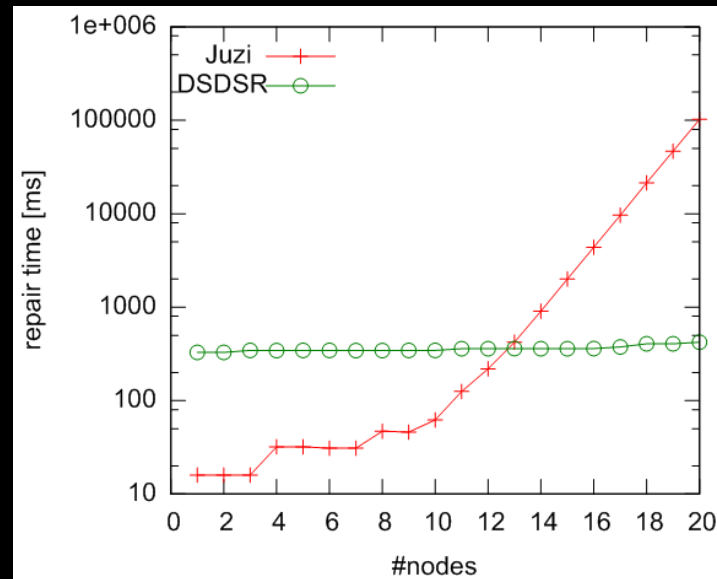

public class Node {
    int value;
    Node next;
    // ..
}

```

First node has a value that is equal to the number of nodes in the list.

## Performance of Juzi and DSDSR for linkedlist

Dynamic Symbolic Data Structure Repair

11

## Another example: Binary tree

```

public boolean repOk() {
    boolean result = true; // An empty tree == zero in size
    if (root == null) {
        if (size != 0)
            result = false;
        return result;
    }
    // ...
    while (!workList.isEmpty()) {
        Node current = workList.removeFirst();
        if (current.left != null) { // no cycles along left
            if (!visited.add(current.left)) {
                result = false;
            } else
                workList.add(current.left);
        }
        if (current.right != null) { // no cycles along right
            if (!visited.add(current.right)) {
                result = false;
            } else
                workList.add(current.right);
        }
    }
    if (visited.size() != size) // size == #visited nodes
        result = false;

    return result;
}

```

- Acyclic along left and right pointers.
- Cannot share nodes.
- #nodes reachable from root along left and right fields is stored in the size field.

Dynamic Symbolic Data Structure Repair

12

## Another example: Binary tree

### Observations:

- Defining correctness properties are hard.
- Writing a correctness condition that checks correctly, easy to read and meets repair specific style – is even harder.
- Juzi requires specific style in correctness condition, namely, last accessed field and instance should be the actual corrupt ones.

Dynamic Symbolic Data Structure Repair

13

## Binary tree: modified repOk - Juzi

```

public boolean repOk() {
  boolean result = true; // An empty tree == zero in size
  if (root == null) {
    if (size != 0) {
      result = false;
      return result;
    }
  }
  // ...
  while (!workList.isEmpty()) {
    Node current = workList.removeFirst();
    if (current.left != null) { // no cycles along left
      if (!visited.add(current.left)) {
        result = false;
      } else {
        workList.add(current.left);
      }
    }
    if (current.right != null) { // no cycles along right
      if (!visited.add(current.right)) {
        result = false;
      } else {
        workList.add(current.right);
      }
    }
  }
  if (visited.size() != size) // size == #visited nodes
    result = false;
  return result;
}

```

- Acyclic along left and right pointers.
- Cannot share nodes.
- #nodes reachable from root along left and right fields is stored in the size field.

Dynamic Symbolic Data Structure Repair

14

### Binary tree: modified repOk - DSDSR

```

public boolean repOk() {
    boolean result = true; // An empty tree == zero in size
    if (root == null){
        if (size != 0)
            result = false;
        return result;
    }
    // ...
    while (!workList.isEmpty()) {
        Node current = workList.removeFirst();
        if (current.left != null) { // no cycles along left
            if (!visited.add(current.left)) {
                result = false;
            } else
                workList.add(current.left);
        }
        if (current.right != null) { // no cycles along right
            if (!visited.add(current.right)) {
                result = false;
            } else
                workList.add(current.right);
        }
    }
    if (visited.size() != size) // size == #visited nodes
        result = false;

    return result;
}
    
```

Constraints:

```

n1 != null
n1.left != null
n1.left != n1  n1.left != n1
n1.right != null
n1.right != n1
n2.left != null
n2.left != n1
n2.left != n2
...
5 == size
    
```

Solve

```

n1.left = new_Node
    
```

size = 5

Dynamic Symbolic Data Structure Repair 15

### Binary tree: modified repOk

```

public boolean repOk() {
    boolean result = true; // An empty tree == zero in size
    if (root == null){
        if (size != 0)
            result = false;
        return result;
    }
    // ...
    while (!workList.isEmpty()) {
        Node current = workList.removeFirst();
        if (current.left != null) { // no cycles along left
            if (!visited.add(current.left)) {
                result = false;
            } else
                workList.add(current.left);
        }
        if (current.right != null) { // no cycles along right
            if (!visited.add(current.right)) {
                result = false;
            } else
                workList.add(current.right);
        }
    }
    if (visited.size() != size) // size == #visited nodes
        result = false;

    return result;
}
    
```

Constraints:

```

n1 != null
n1.left != null
n1.left != n1
n1.right != null
n1.right != n1
n1.right != n6
...
6 != size
6 == size
    
```

Solve

```

size = 6
    
```

size = 6
